Configuration File: config.yml

The script operates in a **Hot Folder** mode, and its main configuration file is config.yml. Before running the script, ensure that you've properly set up this file as follows:

Directory Setup

You need to specify four directories in the config.yml file:

1. **done**: The location where successfully processed files will be saved.

2. **error**: The location where files that encounter errors during processing will be saved.

3. **hotfolder**: The folder where you place files to be processed.

4. **processing**: A temporary folder where files currently being processed are stored.

Worksheet Configuration

For each worksheet in the Excel file, you must configure the following in the sheet_config section so the script knows where to find the required columns:

- **license_index**: The column index for the license data.

- **status_index**: The column index for the status data.

- **last_checked_index**: The column index for the "last checked" data.

Note: Column indices are zero-based. For example, if the license_index is in the first column, the value would be 0.

Save Configuration

The script automatically saves the workbook after processing a certain number of rows. You can control how many rows are processed before each save by adjusting the numrec_before_save setting in the configuration file.
